
EARNKARO · SENIOR PM ASSIGNMENT

Segmentation and Personalization

Making one app feel like it was built for each of 3 million creators.

This is the answer to Question 1. It ships with a working, instrumented prototype (React) — the screenshots throughout are from it. Everything here is built on the real EarnKaro app and a clear point of view: the fix isn't five apps, it's one app that quietly knows who you are.

Prepared by Agniv

Includes: 5 segments · a root-cause audit · a segmented design · flow diagrams · a success and A/B framework · a data model · a live prototype.

THE SHORT VERSION

The whole answer, in one picture

EarnKaro has a three-million-creator problem hiding in plain sight: it treats them all the same. Rohit, who runs a 20,000-member Telegram deal channel, gets the exact same home feed as Sunita, who shares a few grocery deals with her family from home. The argument below runs left to right — and then loops, because the whole thing only works if it learns.

One root cause sits under all of it: the app is organised around its own objects — profit links, partner stores, a transactions ledger — not around the creator (their workflow, their audience, their goal). Fix that, and “built for me” stops being a slogan.

PART 1

Five creator segments

Segments are behavioural, not demographic. “Housewife” or “college student” are labels that sit on top of behaviour; the product should care about how someone actually shares. The clean cut is audience size × monetization intent.

The Deal-Broadcaster e.g. Rohit, runs a 20k Telegram channel

- Who: Runs broadcast channels; posts 30–100+ deals a day. Treats it as a side business.
- Primary goal: Throughput — turn trending deals into posts fast, before they expire.
- What motivates sharing: Money, directly: volume × conversion, and never missing a hot deal.
- A successful week: ~500 links, a few “hero” deals each driving hundreds of clicks, ₹3,000–10,000+.

The Instagram Influencer e.g. Aisha, 40k fashion followers

- Who: Curated niche audience; posts selectively; few shares, high trust per share.
- Primary goal: Earn from her audience without diluting her brand — on-brand products, shared natively.
- What motivates sharing: Money + reputation. She won’t post an ugly link or an off-brand product.
- A successful week: 10–25 curated links, 2–3 story sets, high conversion per link, no clutter.

The Casual Sharer e.g. Sahil, shares in his hostel WhatsApp

- Who: Student/young earner; low volume, opportunistic; came via a referral.
- Primary goal: A little side income with almost no effort; pocket referral bonuses.
- What motivates sharing: Easy money + social ease; saving on his own purchases.
- A successful week: 3–10 links, 1–2 conversions (often his own buys), ₹200–800.

The Power Affiliate e.g. Vikram, treats EK like a business

- Who: Multi-channel, data-driven, runs a referral downline. The top few percent.
- Primary goal: Optimise and scale earnings; grow the network; run EK like a dashboard.
- What motivates sharing: Income maximization + downline growth (the lifetime 10% cut).
- A successful week: 500+ links, deep analytics, ₹15,000+, and he knows why the number moved.

The Home Earner e.g. Sunita, earns from home in Bengaluru

- Who: Homemakers/retirees in trusted groups; time-rich, tech-cautious, often vernacular.
- Primary goal: Reliable supplementary household income, with low complexity. Real money to her.
- What motivates sharing: Income + helpfulness; very sensitive to “will I actually get paid?”
- A successful week: 15–40 links in a few trusted groups, ₹800–3,000, paid without friction.

Which ones do we build for first?

We don't have EarnKaro's internal numbers, so the split below is an explicit estimate — but the point is to decide, not just describe.

Segment	Share of creators	Share of GMV	Role
Casual + Home Earner	Most by headcount	Low each	Top-of-funnel; referral engine; loyal base
Broadcaster	Small	High (volume × conv.)	Core GMV driver
Power Affiliate	Tiny	High	GMV + viral referral flywheel
Influencer	Mid	Medium	Brand credibility; pulls premium brands

Build order: Broadcaster first (biggest GMV lever, clear ROI on throughput) → Home Earner second (largest activation/retention base, cheapest to keep) → Influencer third (growth and brand). The Power Affiliate is mostly served by extending Broadcaster tooling plus a network dashboard.

The one question we ask up front — a soft, skippable signal, not an identity. Behaviour does the rest.

PART 2

Audit: the top 3 problems

Three structural problems — each hits one segment hardest, and each is a different face of the same root cause. (Observations are from the live EarnKaro app.)

Problem 1 — The unit is a profit link, not a ready post

Hits the Broadcaster

- What's actually happening: The app is built around "Make a Link." Rohit can browse deals right inside EarnKaro and copy a profit link, or paste any product URL into "Make Links" to convert it — so getting a link isn't the hard part. The problem is what he gets: a bare link, when his job is to publish a deal — an image, a line of copy, and the link, as one post. EarnKaro hands him the link and leaves the rest to him, by hand, one deal at a time: no one-tap "turn this deal into a post," no bulk convert, and a feed that isn't ranked by what's hot or about to expire. At 30–100 posts a day, that manual assembly is the ceiling.
- What it costs EK: A throughput ceiling on the highest-GMV segment, and a reason for power users to defect to third-party bots.

Problem 2 — Discovery is built around stores, not products

Hits the Influencer

- What's actually happening: The home feed is a wall of store-wide banners — "Myntra End of Reason 50–80%," "Flipkart June Epic Sale." The app's idea of "content" is which store has a sale. Aisha's idea of content is which specific product fits her audience. She has to dig through mega-sales to assemble something on-brand — and the clutter is exactly what she refuses to post.
- What it costs EK: The highest conversion-per-link segment under-shares or churns, and EK loses the brand credibility that attracts premium partners.

Problem 3 — Success is a backward ledger, not a forward goal

Hits the Home Earner (and the Power Affiliate)

- What's actually happening: Reports is a rear-view mirror: "₹30, Pending ₹30, Confirmed ₹0." It tells you what already happened. Nowhere is there a goal, a progress bar, or a "here's the one thing to do today." For Sunita — cautious, vernacular-first — the opaque "pending" states read as "will I even get paid?", and she quietly stops. (Vikram feels it too, and rebuilds tracking in a spreadsheet.)
- What it costs EK: EK leaks a huge, loyal, daily-active base at activation — the cheapest users to keep.

The through-line: one app means the Broadcaster is throttled, the Influencer is cluttered, and the Home Earner is intimidated. That is the real, evidence-backed version of "the product does not know who you are."

PART 3

A segmented experience

One important call first, because it's easy to get wrong: we do not put the segments in the UI. Nobody opens an app thinking "I am a Broadcaster," and a label you can't act on is noise. So the five segments are an internal lens. They show up in two invisible ways:

- Relevance — which deals and categories rise to the top, learned from behaviour.
- Progressive tools — the right tool simply appears: bulk + a clicks dashboard for a high-volume sharer, a story-card maker for an Instagram creator, a goal tracker for a goal-setter.

The only thing we ask up front is a soft, skippable interest signal, to make day one feel relevant before we have data. This is how Instagram and Amazon work — they infer, they don't interrogate. We still answer the literal brief: the home, the discovery, and the sharing tools genuinely differ by segment. Here's how.

Broadcaster — make the unit a post

- Home: a Hot and Expiring velocity feed (what should I post right now?).
- Sharing (the hero): one tap turns a deal into a ready post — image + caption + link — plus bulk select to fire off a dozen at once.

Broadcaster home: velocity feed, a live clicks dashboard, and a bulk bar — speed, not browsing.

Bulk "Broadcast 3 deals" — ready posts handed straight to Telegram or WhatsApp.

Influencer — make the unit a product in her niche

- Home: a curated product board in her niche, not store sales.
- Sharing (the hero): a one-tap story card — a clean, on-brand image + a short link, ready for Instagram.

Influencer home: a product board with a “Create story card” tool front and centre.

The story card: a reputation-safe asset she can post in one tap.

Home Earner — make the unit a step toward her goal

- Home: a monthly goal + progress bar + today's 3 picks, in plain language.
- Sharing: one tap to her saved Family group; payouts written like “₹30 — paid to you by the 7th,” not “pending.”

Home Earner: a goal she's chasing
and three things to do today.

The share sheet — with a
“suggested for you” default per
segment (here, Telegram).

Power Affiliate: the same app, now a dashboard — a 6-week earnings trend and performance up top.

Why these are the right changes (not just nice ones)

Segment	Hero change	Impact / Effort	Beats... (and why)
Broadcaster	One-tap post + bulk	High / Med	A browser extension (off-app, more work) and a scheduler (doesn't fix throughput)
Influencer	Niche feed + story kit	High / Med	Creator analytics first — relevance matters more than charts for sharing
Home Earner	Goal + daily picks	High / Low	Vernacular-only — necessary, but guidance is the activation lever

Each hero change lands on a different surface (sharing / discovery / home) and fixes a different root — no overlap, no wasted effort.

How the experience diverges — a flow

Same front door, same spine (top bar, nav, payments). One soft question routes two very different creators into two very different apps — then both feed the same learning loop.

And because this is a real prototype, every section can explain itself. Turn on “personalization notes” and each block tells you why it’s there and which segments it serves — including the honest cases (a flash-deal timer helps Broadcasters and Casual sharers, so it’s shown to everyone).

Tap any marker and the prototype explains the logic — here, why flash deals with a live countdown serve more than one segment.

PART 5

Does it work? Metrics and an A/B test

North Star — Weekly Active Earning Creators: people who make at least one converting share a week. It only counts if they shared (engagement) and it converted (GMV). Above it sits the business outcome: creator-attributed GMV per week.

Each segment gets a leading indicator that its hero change should move:

- Broadcaster → posts per active day, and how fast a hot deal gets posted.
- Influencer → conversion rate per link, and share of posts using the story kit.
- Home Earner → 14-day activation and the share of creators who hit their goal.

Guardrails (must not break): conversion rate per link, spam/unsubscribe and partner complaints, payout tickets. The counter-metric we watch hardest: clicks that don't convert must not rise — that's noise, not value.

The experiment

- Test: the adaptive experience (soft onboarding → adaptive home + default share tool) vs. today's one-size app.
- Control: the current app — generic home, paste-a-link tool, no onboarding question.
- Randomise: by creator, at sign-up. New users give the cleanest read; existing users have habits that would muddy it.
- Primary metric: % of new creators with a converting share within 14 days. Roughly a 25% baseline; to catch a +2.5pp lift at 80% power needs about 4,800 creators per arm — run 4-6 weeks.
- A meaningful result: primary beats control by the MDE ($p < 0.05$), no guardrail breach, and the per-segment indicators move the right way — proof it's personalization, not a novelty bump.

One honest extension: the biggest GMV upside is in existing power users, so a second test runs a creator-level holdback on them — measuring sustained week-4 behaviour (to net out novelty) and watching for GMV simply shifting between creators. New-users = the clean read; existing-users = the value read.

The data engine that makes it smarter

Start with the constraint that makes EarnKaro special — and that most answers miss. Creators share links out to WhatsApp, Telegram and Instagram, where EK cannot see impressions, audiences, or engagement. We only see two things: what happens in-app, and the click-then-conversion when a buyer comes back through the link. The signal is sparse and one-sided — so the model has to be designed around it.

So we lean on what we own: in-app browsing and affinity, the creator’s link-creation choices (which brand, category, and — crucially — which channel they pushed to), and the click-to-conversion outcome of every link. The channel a creator shares to is our best off-platform proxy: we may not see the group, but we know where they sell. A neat side-effect: the more we pull sharing into in-app surfaces (the story card, the post composer), the more of the funnel we recapture.

The data model

- Creator — declared signal, plus an inferred segment with a confidence score, language, channels, goal.
- Creator feature profile (the part that learns) — category and brand affinities, channel mix, personal conversion rate, active hours. Recomputed on every interaction; it’s the bridge between raw events and what the feed ranks.
- Deal, Brand, Link, Outcome, Referral, Event — the supporting objects and the append-only event log.

How it improves with each interaction: the onboarding answer is just a prior. If Sahil ticks “Casual” but then posts 80 deals a day to a 20k group, behaviour overrides the label and he’s re-scored toward Broadcaster — his home and tools shift with him. Early on we serve the segment template; as the profile fills, ranking moves from “what Broadcasters like” to “what this creator converts.” Rules run it today; ML (learning-to-rank, conversion-propensity) earns its place once the log beats the rules.

We made this tangible: the prototype fires real events and shows them live, with a full inspector of everything captured per interaction.

Every section is tagged with the event it emits, and the live stream logs them as you tap — the tracking plan, made visible.

The event inspector: per-event detail plus the user and device properties we'd capture (session, device, OS, city, lat/long, IP).

Risks we'd watch

- Filter bubble. Over-personalising narrows the feed. Keep a few exploration slots so creators still discover new categories.
- Cold start and sparse signal. Early guesses are weak (see Part 6). Lean on the declared signal and safe defaults until confidence is high.
- Over-fitting to the past. Audiences shift; decay old signal so last month doesn't trap a creator forever.
- Fairness to brands. Ranking can starve mid-tail deals. Add a brand-diversity guardrail so the catalogue doesn't collapse to a few winners.
- Trust, for the Home Earner. Wrong picks erode trust fastest for the most cautious segment. Stay conservative and always show "why you're seeing this."

In one line

Five segments, one app, no labels. The home, the discovery, and the sharing all bend to who you are — a Broadcaster gets speed, an Influencer gets taste, a Home Earner gets a goal — and a sparse-but-honest data loop makes every one of those guesses a little better next week.

APPENDIX

- Prototype: interactive React app — onboarding into five adaptive homes, divergent share flows, light/dark, and a live event stream. A hidden "simulate profile" control lets a reviewer watch the same app re-personalize (not a user feature).
- On the numbers: segment sizes and the A/B baseline are explicit estimates, to be replaced with EarnKaro's own data.

The Instagram Creator Feature Suite

Turning a creator who shares one deal a week into one who ships five.

This is the answer to Question 2. Three features — an AI Reel Maker, Auto DM, and a Link-in-Bio Storefront — each own one stage of the creator funnel, and they're wired together so making a Reel arms the DM and feeds the storefront. It ships with a working prototype, a live unit-economics calculator, and a clear point of view: the moat isn't "AI", it's EarnKaro's data about what actually converts.

Prepared by Agniv

Includes: exact flows (creator-does / EarnKaro-does) · the AI per feature · technical feasibility · 30/60/90 success metrics · a financial model + live calculator · backend flow diagrams · what I'd ship first.

THE SHORT VERSION

The suite, in one picture

A creator's path to earning is a funnel: discover a deal → create content → distribute it → convert the audience → get paid. Today EarnKaro owns the first step and half the second — it hands you a link. Everything else happens in other apps. That gap is why a creator who could share five deals a week shares one. The suite closes the funnel, one feature per stage.

Why EarnKaro and not Creatify + ManyChat + Linktree? Those generic tools exist. EarnKaro's unfair advantage is data they don't have: the live deal catalog, the commission economics, and — the big one — what actually converts. “AI-native” here doesn't mean a bolted-on chatbot; it means the AI is fed by EarnKaro's proprietary signal. That's the moat, and it runs through every feature.

Throughout, one creator: Aisha — fashion, ~40k Instagram followers — sharing a specific Myntra deal (a ₹4,999 dress, down from ₹8,999).

How a creator finds the suite

Discovery is personalization-led — the same engine from Q1 that infers who is an Instagram creator surfaces a Creator Studio (Reel Maker, Storefront, Auto DM, Identity, analytics) only for creators like Aisha. Rohit the Telegram broadcaster never sees it. We surface the suite by segment; we don't lock it behind a label.

The entry points

- From any deal — a “Make a Reel” button on the deal page, a quick-action on deal cards, and inside the Share sheet. The deal is the seed.
- Creator Studio tab — the home for the whole suite, surfaced to inferred IG creators.
- A share-extension from a partner site, and a lifecycle nudge (“your last reel drove 1,840 clicks — make another”).
- First-run is a guided “make your first reel in 30s” on a sample deal; every run after is one tap.

Nudges that move a creator from sharing one deal to opening the suite

Notifications are the bridge from Q1's home to the suite. A few we'd send (push + in-app), each tied to a real trigger and an honest number:

Trigger	Notification copy	Goal
Connected IG, no reel yet	“You're set up. Make your first Reel from today's top deal in 30 seconds →”	Activation
A reel did well	“Your saree Reel drove 1,840 clicks Make another from a trending deal?”	Repeat use
Comments piling up	“23 people asked for the link on your Reel. Turn on Auto DM and never miss one.”	Auto DM
Storefront idle	“Your bio link is empty. Add your 5 best deals — it stays live and never goes dead.”	Storefront
Deal expiring	“The dress you posted sells out tonight. One tap to re-share before it's gone.”	Velocity

Guardrail: these are frequency-capped and earned by behaviour — the same data loop that personalizes the home decides who is worth nudging, so we don't spam the base.

Discovery is personalization-led: the home surfaces a Creator Studio card only to creators who post to Instagram ("we surfaced this because you post to Instagram").

PART A

How each feature works

For each feature: what Aisha does, and what EarnKaro does in the background.

A1 · AI Reel Maker — fixes create

What Aisha does

- Opens the dress deal, taps Make a Reel. (First time only: one Instagram OAuth.)
- Picks a path: Without Aisha (product-only b-roll + voiceover, free), With Aisha — record a hook (a real 3-5s selfie clip stitched to AI b-roll, free, authentic), or With Aisha — saved clone (her cloned voice/face in one tap, Pro).
- Optionally nudges tone, length (15-30s), or the hook line; previews and tweaks; taps Post.

What EarnKaro does in the background

- Pulls the real product images from the partner catalog (never AI-invented) + the structured deal data.
- An LLM writes a short script grounded only in that data — no fake claims — with the #ad disclosure and a comment-to-DM CTA baked in.
- ElevenLabs turns the script into a voiceover; the assembler builds the 9:16 video (motion, burned-in captions, price/discount text, licensed audio, ≤90s).
- On post, it binds the deal's profit link to the Reel and auto-arms the Auto DM. Making the Reel is setting up the funnel.

The decoupled-identity rule (“no-load”).

The cloned voice/face is never captured inside the creation flow. It lives in a dedicated Creator Identity section, unlocked with Pro, set up once (a ~1-3 min voice sample + a short clip), reused in one tap. A per-reel override lets her record a fresh hook without touching her saved identity. So making a reel never stalls on a capture — the heavy, consent-bound setup happens deliberately, elsewhere, once. (Why gate behind Pro: cloning carries real compute cost; gating aligns cost with revenue and avoids cloning free users who may never convert.)

Inside Creator Studio, every deal carries a one-tap “Make a Reel.”

Choose a path: “With you” (your face + voice, Pro) or “Product only” (AI b-roll + voiceover, free).

A2 · Auto DM — owns convert

What Aisha does

- Nothing. The auto-written caption already says “Comment LINK and I’ll DM you the deal.” (She can edit the keyword or DM copy if she wants.)

What EarnKaro does in the background

- Subscribes to comment webhooks on that post via the Instagram Messaging API.
- On each comment, an LLM classifies intent — not just the literal keyword, but “price?”, “where to buy”, “size M?”, “ need this.” Clear buying intent triggers; chatter doesn't.
- Posts a public reply (“Sent ✓”) and sends a private-reply DM with the tracked profit link. The comment is the follower's explicit opt-in — which is exactly what makes the DM compliant.
- Tailors the DM using deal data (a “size?” gets variants; a “promo?” gets the code) and attaches 2 related deals + her storefront link. Every click is a tracked profit link → an attribution event.

Isn't this just the Graph API? No — what makes it a product, not plumbing

The comment→DM mechanism is a commodity — ManyChat runs on the same API. EarnKaro isn't selling the plumbing; four things make ours different, and none are replicable by a generic tool:

	EarnKaro Auto DM	ManyChat / raw Graph API
The link	Live, tracked, commission-bearing profit link bound to the deal	Whatever static URL you pasted — no deal awareness

The reply	Intent + deal-aware: “size M?” → the variant link; “promo?” → the code	Fires on a literal keyword, sends one fixed reply
Setup	Zero — the Reel Maker auto-arms it and binds the link	A separate tool, configured per post
The loop	Every click feeds “what converts” back into the suite	No commission/conversion data

Auto DM in action: a buying-intent comment gets a public “Sent ✓” and a private-reply DM carrying the tracked profit link.

A3 · Link-in-Bio Storefront — the always-on distribute + convert surface

What Aisha does

- Opens My Storefront, adds deals to collections (“Festive picks”, “Wishlist”), sets a seasonal hero, reorders, toggles what's visible. Her Reels and wishlist can auto-flow in.
- Copies her one link — earnkaro.shop/aisha — and pastes it in her Instagram bio. Done.

What EarnKaro does in the background

- On publish, renders a fast hosted page (CDN), binds every product to her profit link, and registers a live-sync job.
- Continuously re-checks the catalog: updates price/stock, prunes expired deals, recalculates commission — so the bio link is never dead (the failure mode of every Linktree).
- On a visitor tap, “Buy” fires the tracked profit link → partner redirect with her tag → an attribution event (visitor, product, source=storefront, referring Reel).

The storefront: curated collections + a live deals strip, every product on her profit link.

WORKED EXAMPLE

Aisha's ₹4,999 dress, end to end

To keep this out of the high-level register: here is the actual trace for one deal — the real data in, the real artifacts out, at each step.

1 • The deal record EarnKaro already holds (the input)

```
{ deal_id: "DZ8821", title: "Sangria Floral Wrap Midi Dress", brand: "Sangria",  
  mrp: 8999, price: 4999, discount: "44% off", category: "Dresses > Ethnic",  
  sizes_in_stock: ["S","M","L","XL"], promo: "EXTRA10", commission_pct: 8,  
  profit_link: "ek.deal/DZ8821?cr=aisha", images: [pdp1, pdp2, pdp3],  
  expires: "2026-06-22" }
```

2 • The prompt skeleton to the LLM (grounded — facts only)

“Write a 20s Instagram Reel script for a fashion creator. Use ONLY the facts in the deal record below; invent nothing. Tone: warm, second-person, light Hinglish. Include a hook, two product beats, the price + discount, the #ad disclosure, and the CTA ‘comment LINK’.” → [deal record]

3 • The script it returns

- Hook (0–3s): “Okay, this wrap dress is unfair.”
- Beat 1 (3–9s): “Sangria floral midi — the print, the drape, festive-ready.”
- Beat 2 / price (9–15s): “₹8,999 down to ₹4,999. 44% off.”
- CTA (15–20s): “Comment LINK and I'll DM you the deal. #ad”
- Caption: “Festive-ready & under ₹5k. Comment LINK for the deal. #ad”

4 • Voiceover

ElevenLabs Flash, voice=aisha_clone (or a library voice), ~270 chars ≈ ₹2 → a 19.4s vo.mp3.

5 • Assembly (v1 templated)

pdp1 0–3s (slow zoom) · pdp2 3–9s (pan) · pdp3 9–15s · a price card overlays 9–15s · a CTA card 15–20s · captions burned in · licensed track at –18 dB · export 1080×1920, 20s.

6 • On post

Bind `ek.deal/DZ8821?cr=aisha` to the Reel; auto-arm Auto DM (keyword LINK + intent) on the new `media_id`.

Then the Auto DM, on real comments

Comment	Classifier label	What EarnKaro sends
“LINK”	explicit keyword → fire	The tracked link
“how much?? ”	buying intent → fire	“It's ₹4,999 (44% off) → [link]. Sizes S–XL.”
“does it come in M?”	variant query → fire + tailor	“Yes, M's in stock → [link]”
“gorgeous”	chatter → ignore (no spam)	—

The Storefront sync job — why the bio link never dies

Every ~6h (or on a partner webhook) it re-fetches each pinned product's price/stock/commission, prunes expired cards (swapping in the next from that collection), updates price badges, recomputes her profit link, and re-ranks “your best converters.” So the ₹4,999 dress quietly leaves her bio at 00:00 on 23 Jun — she does nothing.

The AI component, per feature

The trace above is the concrete version of this section; here is the same machinery, generalised per feature — what powers it, the data it uses, and how it improves.

Reel Maker

- What powers it: An LLM for the script (GPT/Claude class; self-hosted Llama once volume justifies it), ElevenLabs for TTS + voice cloning, and a video model for v2 motion (Veo 3.1 / Runway / Kling). v1 uses deterministic templated motion — cheaper, faster, can't distort the product.
- What data it uses: EarnKaro's structured deal data (the differentiator), the real PDP images, Aisha's niche and past-caption style, and — over time — which scripts/hooks/voices converted.
- How it improves: It learns which hooks, lengths, voices and styles drive the most clicks and GMV, per niche — so Aisha's third Reel is better-tuned than her first.

Auto DM

- What powers it: A lightweight LLM intent classifier (cheap per call; ideal to self-host at scale).
- What data it uses: The comment text + the post's deal context (product, variants, price, promo, commission).
- How it improves: It learns which comment patterns convert, which DM copy gets clicks, and the best related-deal to attach — raising click-through per comment over time.

Storefront

- What powers it: A ranking/recommendation layer over the catalog + Aisha's curation.
- What data it uses: Her curation, live catalog state, her audience's behaviour, and conversion history.
- How it improves: It learns which products convert for her audience and re-ranks; v2 personalizes to the individual visitor (the Reel they came from).

The identity call — the honest version

Voice cloning (ElevenLabs) is worth it — cheap after setup, lower-risk, sounds like her. A fully synthetic face/avatar (HeyGen-class) is not the v1 default: it's expensive, risks the uncanny valley and an authenticity backlash (her audience follows her), and triggers Meta's AI-content label. So “With Aisha” v1 = her real recorded hook + AI b-roll (optional cloned voice); the synthetic avatar is a v2, opt-in, clearly-labelled experiment.

The common thread: every feature's AI is sharpened by the same proprietary signal — what converts — which generic tools simply don't have.

Instagram-matched deal recommendations

One capability that falls out of the Instagram connection almost for free — and ties Q1's personalization to Q2's new signal. Today a creator like Aisha has to hunt through mega-sales for something on-brand (the Q1 discovery problem). Once she's connected Instagram, we close it: Creator Studio leads with deals matched to her niche.

The signal — and the honest limit

The Instagram Graph API exposes her own account — recent media, captions, hashtags, basic profile — not arbitrary scraping of anyone else. We read her own posts and hashtags, classify her niche (here: fashion & beauty), and match it to EarnKaro's catalog by category and brand affinity. “Based on her Instagram” means her consented, first-party content — which is exactly what keeps it compliant.

The AI + the loop

A lightweight classifier turns her captions/hashtags into a niche + affinity profile; we rank catalog deals by that affinity and by what converts for similar creators — the same proprietary signal as everything else. Over time it personalizes to her from her own conversion data (the Q1 feature profile), so the recommendations sharpen the more she shares.

Why it matters

It collapses the funnel's first step — discover — for the highest-trust, hardest-to-please segment (the Influencer). She stops digging through store-wide banners; the on-brand deals come to her, ready to turn into a Reel in one tap. It lifts GMV at the cheapest point: better-matched deals convert better and feel authentic to her audience.

Compliance & graceful degradation

Reading her media needs explicit consent at Instagram connect (DPDP: purpose-limited, revocable); we store the derived niche, not a copy of her content. If she's connected but posts little, it falls back to the Q1 behavioural personalization — so the feature never blocks, it only adds.

What happens in the background — the flow

Two decision trees carry the load. The first is the Reel Maker pipeline (the work that turns one tap into a posted, fully-armed Reel). The second is Auto DM (turning a comment into a tracked, compliant sale). Diamonds are decisions; the teal end-nodes are where EarnKaro's data loop closes.

Making the reel sets up the funnel — the loop generic tools can't copy.

Convert the audience — Auto DM

UNDER THE HOOD

How the Creator Suite decides

◆ decision ■ step ■ cost / Pro ■ conversion

CREATE THE REEL

CONVERT THE AUDIENCE

Two decision trees — creating the reel (left) and converting the audience (right). Diamonds are decisions; the dashes flow along the path the data takes. Instagram is simulated in the demo; the logic above is what production runs.

The same architecture, animated in the live prototype — open it from the Q2 flow to watch a tap travel through the pipeline.

Technical feasibility — APIs, SDKs, constraints

This is buildable on documented, production APIs today — but each carries a real constraint that shapes the product. Naming them is the point.

Reel Maker

- Build on: an LLM API (script), ElevenLabs (TTS + voice clone), a video-gen API for v2 (Veo 3.1 / Runway / Kling), a templated renderer (ffmpeg/Remotion) for v1, and Instagram's Content Publishing API to post.
- Constraints: auto-publish only works for Instagram Business accounts — many creators are on Creator accounts, so the realistic default is “export to the IG composer,” with auto-publish as a Business upsell. 100 API posts/24h, Reels ≤ 90 s. Video-gen latency and cost (the unit-economics driver). Music must be licensed. Voice/face cloning needs explicit, revocable consent + secure storage (India DPDP Act), and AI reels likely need Meta's AI-content label. Don't build on Sora (API sunsets Sept 2026).

Auto DM

- Build on: Instagram Messaging API (Graph API) — comment webhooks + private replies; permissions `instagram_manage_messages`, `instagram_manage_comments`; requires a Business/Creator account and Meta app review + business verification.
- Constraints: the private-reply mechanism (one reply per comment, inside the allowed window), ~200 automated DMs/hour, and Meta's strict stance on unsolicited messaging — so intent-based triggering must stay tight (clear buying intent only) to avoid spam-flagging. Plan for app-review lead time.

Storefront

- Build on: a standard web stack (hosted page + CDN), the existing EarnKaro profit-link/affiliate engine, and a catalog-sync service. No special Meta API needed.
- Constraints: Instagram allows one bio link, so it must be a single fast URL; deep-linking into partner apps for conversion; catalog freshness depends on partner feed latency.

Cross-cutting: Instagram OAuth is the shared unlock; AI content may need Meta's AI-generated label; affiliate posts need #ad disclosure (ASCI/FTC).

Privacy & compliance — the DPDP Act

This suite handles sensitive personal data, so India's Digital Personal Data Protection Act, 2023 is a first-class design constraint, not a footnote. The DPDP Rules, 2025 were notified on 13 Nov 2025 and roll out in phases — the Data Protection Board first, Consent Manager registration ~Nov 2026, and the core obligations (notice, security, breach reporting, Data Principal rights) ~May 2027. We'd be building into a regime that tightens over the exact window this suite ships — so design for it now.

- Voice/face cloning = biometric personal data — the highest-sensitivity data we hold. Capture explicit, purpose-limited, revocable consent in the decoupled Identity section, store the clone encrypted, honour the right to erasure (delete the clone + derived artifacts), and never reuse it for an unagreed purpose. This is why cloning lives behind a deliberate, separate setup.
- Auto DM = processing the follower's data, not just the creator's. The comment is the lawful basis (explicit opt-in), but we still owe notice (the public reply makes the DM expected, not unsolicited), data minimisation (don't retain comment/DM content beyond the request), and a clear opt-out. EarnKaro is the data fiduciary — the creator isn't carrying that liability alone.
- The data loop = retention + minimisation — keep behavioural data only as long as useful, store inferences (segment, affinities) as derived data a user can see and contest, and collect no more than the model needs.

Operationally, a real launch plans for a consent mechanism / Consent Manager integration, a breach-notification process, and — if EarnKaro is classified a Significant Data Fiduciary at its scale — a Data Protection Officer + grievance route and periodic audits. None of this blocks the build; it shapes the consent UX and the data schema, which is cheapest to get right on day one.

Success metrics — 30 / 60 / 90 days

Three lenses: Adoption (did they try it?), Engagement (do they come back, and does the 1→5 sharing behaviour move?), and GMV uplift (incremental creator-attributed GMV vs a holdout baseline). The North Star for the suite: incremental GMV per active creator.

	Day 30 — Activation	Day 60 — Engagement	Day 90 — GMV proof
Question	Did creators try it?	Are they coming back?	Did it move the money?
Target	30-40% of connected creators use ≥1 feature; first Reels posted; Auto DM live on a meaningful share of posts.	Median deals-shared-per-week rising 1 → 2-3; Auto DM click-through stabilising; week-4 feature retention holding.	+30-50% creator-attributed GMV for active suite users vs baseline; early Creator Pro conversion.
Read	Leading indicators only.	Retention + behaviour change.	The number that matters.

These are targets to validate, not promises — explicit hypotheses to test against EarnKaro's data. The discipline: each day-mark has one question, and we don't claim GMV proof on day 30 when all we have is activation.

Unit economics & pricing

Price by cost. The storefront is ~free to run, Auto DM is ~free per action, and the Reel Maker is the cost driver (video-gen + TTS + tokens). Everything in the pricing falls out of that one fact. (All tool costs bill in USD; FX ₹94.6/USD, 17 Jun 2026, editable in the calculator.)

The cost stack, per feature

Feature	Cost components	Reference unit cost
Reel Maker — v1 (templated)	LLM script + ElevenLabs TTS + render compute. No video-gen model.	~₹7 / reel
Reel Maker — v2 (generative)	v1 + a video model (Kling ~\$0.10/s) for ~15-20s	~₹95-₹255 / reel
Auto DM	One small-LLM intent call per comment + messaging infra (free API)	~₹0.02 / DM
Storefront	CDN/hosting + catalog sync	~₹10 / creator / mo

The single most important finding: the templated reel is ~₹7 (cheap enough to give away); the generative reel is 15-35× more expensive and must be metered (credits), never free. That's why v1 ships first and v2 is a paid add-on. A typical Pro creator's month — 25 templated reels (₹175) + Auto DM (negligible) + storefront (₹10) ≈ ~₹185-₹250 to serve.

Tool choice — what we use, and why not the others

Option	Price	Verdict
Kling 3.0	\$0.10/s	Primary (v2). Best cost + multi-shot consistency for product b-roll.
Runway Gen-4.5	\$0.15/s	Alternate for creative control.
Veo 3.1 Fast	\$0.15/s	Use for the “with Aisha” path (native audio / lip-sync).
Wan 2.6	\$0.05/s	Cheapest; keep as a draft/fallback tier, lower fidelity.
Sora 2	\$1/clip	No — API sunsets Sep 2026.
ElevenLabs Flash (TTS)	\$0.05/1k chars	Chosen for quality + voice cloning; prices fell ~55% in 2026.
GPT-4o-mini / Haiku (LLM)	cents/1k	Scripts + intent; self-host Llama for Auto DM at scale.

Pricing recommendation

Creator Pro: priced by cost, undercuts the DIY stack >10x

DIY stack — Creatify + ManyChat + Linktree

EarnKaro Creator Pro

...of which, cost to serve

At ₹599 price and ~₹225 cost to serve, gross margin ≈ 62%.

The free tier (storefront + basic Auto DM + ~5 templated reels) runs on the cheap templated path (~₹7/reel); the costly generative path is isolated behind credits.

Free where it drives GMV, paid where it drives cost.

Tier	What's included	Price (₹)	Cost to serve	Margin
Free	Full storefront, basic Auto DM, ~5 templated reels/mo	₹0	~₹45/mo	paid by GMV
Creator Pro	High-volume reels, cloned voice, intent Auto DM + analytics, premium storefront	₹599/mo	~₹200-250/mo	~55-65%
Gen. credits	v2 cinematic reels, à la carte	~₹199-249/reel	~₹175/reel	thin (cost-recovery)

Why this works: we undercut the ₹7,850/mo competitor stack (Creatify + ManyChat + Linktree) by >10×, and keep margin healthy because the Free/Pro tiers run on the cheap templated path while the expensive generative path is isolated behind credits. The strategic frame in one line: free where it drives GMV, paid where it drives cost.

A live, editable calculator

The panel can edit every assumption — component unit costs, FX, volumes per creator, ops overhead — and drag a profit-margin slider to watch the suggested Creator Pro price recompute live against the competitor benchmark. It's entry point #3 of the prototype.

What I'd ship first — and the tradeoff I'm naming

Ship Auto DM first. It lifts conversion on content creators already make (so it doesn't depend on AI-video quality being perfect), it acts on traffic the creator already generates (comments on existing posts) rather than waiting for them to build something, its cost per action is tiny, and — the strategic one — it's the highest-frequency touchpoint in the suite (every comment), so it starts the “what converts” data flywheel earliest. That flywheel is the moat that later sharpens the Reel Maker and Storefront. It also forces us to build the Instagram-connection + messaging infrastructure the rest of the suite needs anyway.

Why Auto DM and not the Storefront first?

Fair challenge — the Storefront is the more defensible feature (an auto-maintained, never-dead bio link is impossible without owning the catalog) and the cheapest to run. But it's passive: its GMV depends on the creator driving traffic to a single bio link. Auto DM converts attention the creator is already getting, produces measurable GMV lift on day one, and generates far richer per-comment conversion signal. So the Storefront is #2, not #1 — it's the always-on destination the DMs and Reels point at, most valuable once there's traffic to send to it. Sequence: Auto DM → Storefront → Reel Maker.

The tradeoff, named

The assignment's stated core problem is the content-creation drop-off (creating a Reel is hard, so creators share 1 instead of 5). Auto DM does not fix that — the Reel Maker does. So shipping Auto DM first means deliberately solving the conversion problem before the creation problem, trading “biggest problem” for “fastest, safest proof + the infrastructure foundation.” That's a real tradeoff, and I'd rather state it than pretend the sequence is obvious.

Order	Feature	Why here
1	Auto DM	Wedge + infra. Rides a proven API, lifts conversion on existing content, tiny cost, builds the IG-connection backbone.
2	Storefront	Cheap, foundational, an always-on destination for DMs and Reels to point at.
3	Reel Maker	Highest value on the core problem, but highest effort/cost/risk — shipped once the first two have built the audience and the data.

Risks we'd watch

- Meta policy & app review. Messaging and publishing both need review + business verification; the spam stance is strict. Mitigate with tight intent-triggering and lead-time planning.
- Auto-publish gap. Only Business accounts can auto-publish; export-to-composer is the honest default for the Creator-account majority.
- Cloning consent & authenticity. Voice clone yes; synthetic face is opt-in, labelled, gated — her audience follows her.
- Generative-reel cost. 15–35× the templated path — must stay metered behind credits or it eats the margin.

In one line

Three features, one funnel: the Reel Maker fixes create, Auto DM owns convert, the Storefront is the always-on surface — and because they're wired together and fed by EarnKaro's data on what converts, the suite is something Creatify + ManyChat + Linktree can't be: native, and getting smarter every week.

APPENDIX

- Prototype: an interactive React flow — discover the suite from the Q1 home, make a Reel, watch the Auto DM fire, browse the storefront, and open the animated backend architecture. Plus a live unit-economics calculator.
- On the numbers: all unit costs, the 30/60/90 targets, and the pricing are explicit hypotheses to validate against EarnKaro's vendor contracts and usage.
